Abstract

This work is the result of many years investigations into the problems of understanding how living systems make use of electromagnetic fields and frequencies and into the physics underlying homoeopathy. Water is essential to life as we know it. Living systems have extremely high electric fields across membranes in an aqueous environment, and use electrical communication systems such as nerve impulses. From QED theory, Del Giudice and Preparata have proposed that water has domains of coherence in the ground state as a fundamental property. The novelty in the present paper is in the experimental application of the properties of coherence to coherent frequencies in water and living systems and to mathematical operations on them.

Clinical effects were first obtained in 1982 with water after it had been exposed to a magnetic field and magnetic vector potential at a patient specific frequency thereby putting homoeopathy in the realm of quantum physics and not chemistry. Living systems were found to respond to single a quantum of magnetic flux, to have properties resembling a Josephson Effect and to be sensitive to the magnetic vector potential.

The details of the techniques for writing or imprinting a frequency into water have been established and also for reading, changing, concealing and erasing such an imprint. The latter can be effected by briefly shielding the geomagnetic field. This implies that a parallel/antiparallel alignment of 'qubits' has been thermalised. The liquid nature of water requires that its memory be non-local. A possible physical basis for water memory is line-splitting in far-infrared rotational spectrum of water appearing at other frequencies through coherence. Once coherence is established in a system, the constant parameter becomes the coherence length. Velocity becomes proportional to frequency with no obvious upper limit. Many frequencies and velocities become possible and interactions may occur at widely differing frequencies.
